INTRODUCTION and RAPID FIRE MODEL OVERVIEW

This technical summary provides an overview of the key features and functionality of the *Rapid Fire* model developed by Calthorpe Associates as part of the Vision California planning process. The Rapid Fire model was designed to produce and evaluate high-level statewide and/or regional scenarios across a range of metrics. This document is intended to impart a fundamental understanding of how Rapid Fire scenarios are formulated and analyzed. A more detailed description of the model, including a step-by-step tour through the model's user interface and technical information about all model calculations and assumptions, is available in the *Rapid Fire White Paper and Technical Guide*.

The Rapid Fire Modeling Framework

The Rapid Fire model emerged out of the near-term need for a comprehensive modeling tool that could inform state and regional agencies and policy makers in evaluating climate, land use, and infrastructure investment policies. Results are calculated using empirical data and the latest research on the role of land use and transportation systems on automobile travel; emissions; and land, energy, and water consumption. The model constitutes a single framework into which these research-based assumptions can be loaded to test the impacts of varying land use patterns. The transparency of the model's structure of input assumptions makes it readily adaptable to different study areas, as well as responsive to data emerging from ongoing technical analyses by state and regional agencies.

The model allows users to create scenarios at the national, statewide, or regional scales. Results are produced for a range of metrics, including:

- GHG (CO₂e) emissions from cars and buildings
- Air pollution
- Fuel use and cost
- Building energy use and cost
- Residential water use and cost
- Land consumption
- Infrastructure cost

The Rapid Fire model is not meant to replace more complex travel models or map-based models; rather, it is designed to fill a timely need for defensible comparative analysis that can inform land use and climate policy development and provide a credible and flexible sounding board for state and regional entities as they review and analyze plans and policies. More information about model results and the Vision California process can be found at www.visioncalifornia.org and at www.calthorpe.com/vision-california.

This document starts with an overview of the operational flow of the model, continues with an explanation of how study areas are set and how scenarios are composed, and finally describes how assumptions are applied to calculate results in each metrics category.

The screenshot displays the 'Scenario Definition: Land Use Options & Policy Package Selection' spreadsheet. It is divided into two main sections: '1. DEFINE LAND USE OPTIONS' and '2. SELECT POLICY PACKAGE(S)'. Section 1 includes 'LAND USE OPTION DEFINITIONS' with columns for Urban, Compact, and Sprawled, and 'LAND DEVELOPMENT CATEGORY (LDC) PROPORTIONS' with columns for Single Family Detached, Single Family Attached, and Multi-Family. Section 2 includes 'TRANSPORTATION' with columns for Fuel Efficiency, Fuel Price, and Fuel Cost, and 'RESIDENTIAL & COMMERCIAL BUILDING ENERGY' with columns for Energy Use and Cost. The spreadsheet contains various numerical values and formulas, with some cells highlighted in yellow and blue.

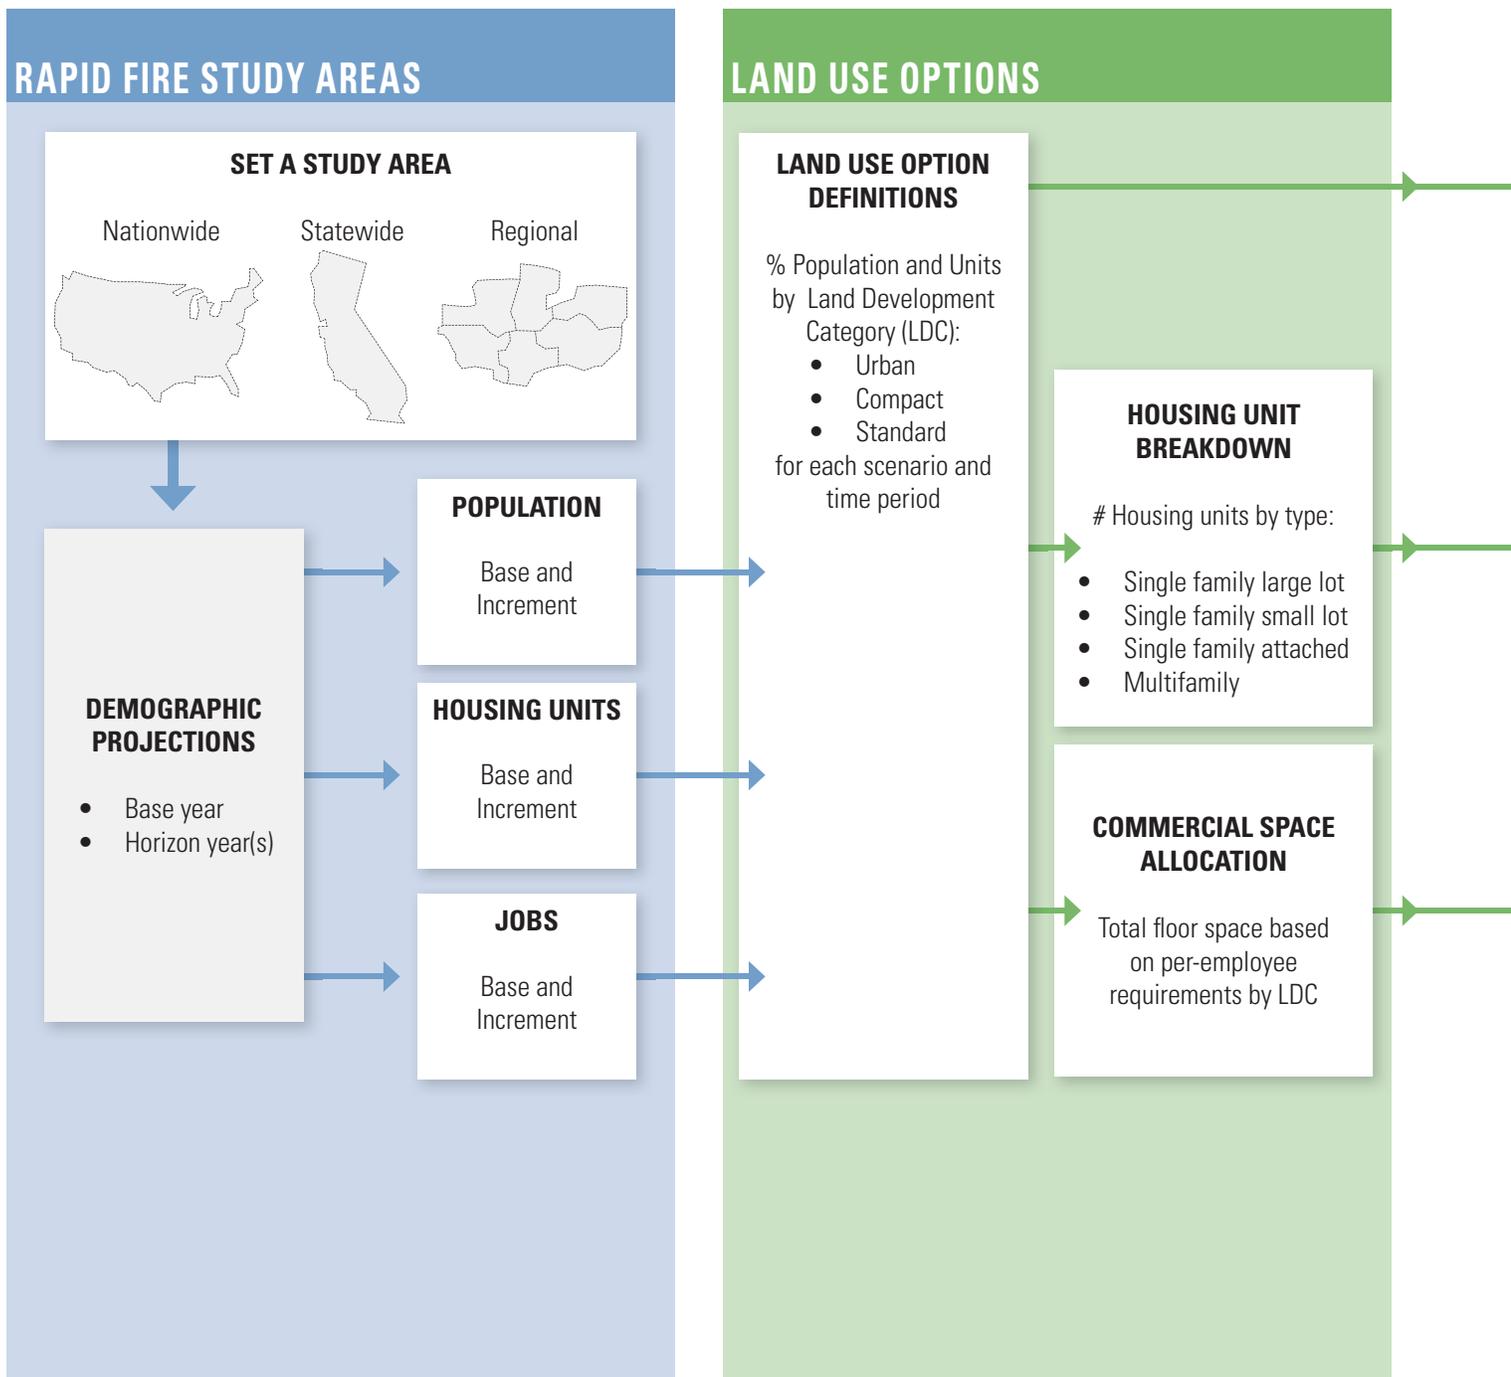

Technical Requirements. The *Rapid Fire* model is a user-friendly, spreadsheet-based tool that allows for efficient testing of different combinations of compact, urban, and more sprawling growth. The model, which runs in Microsoft Excel, is designed to be flexible and transparent. All assumptions are clear and can be easily modified or customized.

RAPID FIRE OPERATIONAL FLOW

From Input Assumptions to Output Metrics

The Rapid Fire model uses a full range of inputs, from demographic projections to travel behavior projections to technical factors for fuel and energy emissions, to calculate output metrics that demonstrate the relative effects of different land use scenarios and policy options. The following chart gives an overview of the operational flow of the model, starting from the selection of a

study area, through the application of land use options and policy packages, to the final stage of metrics output. The chart generally categorizes the input assumptions by type; all assumptions are discussed in greater detail in the later sections of this paper.

POLICY PACKAGES

OUTPUT METRICS

Per-capita assumptions by Land Development Category

LAND CONSUMPTION METRICS

- Land consumed: total, per household, and per capita

INFRASTRUCTURE COST METRICS

- Infrastructure cost: total, per household, and per capita

TRANSPORTATION METRICS

- Light Duty Vehicle (LDV) Vehicle Miles Traveled (VMT)
- GHG and criteria pollutant emissions
- Fuel use
- Fuel cost

Per-unit assumptions by Housing Type

WATER USE METRICS

- Residential water consumption
- GHG emissions from water-related energy
- Household water costs

ENERGY USE METRICS

- Residential electricity and gas consumption
- GHG emissions
- Household energy costs

Per-square foot assumptions

ENERGY USE METRICS

- Commercial electricity and gas consumption
- GHG emissions

Greenhouse Gas (GHG) Emission Rates

- Auto fuel emissions: Tank-to-wheel per gallon; well-to-wheel per gallon
- Electricity emissions per kWh
- Natural gas emissions per therm

TOTAL GHG EMISSIONS

Sum of:

- LDV VMT emissions
- Residential energy use emissions
- Commercial energy use emissions

RAPID FIRE STUDY AREAS

Study areas can range in size, from the local to the national scale, so long as data are available. Study areas are defined by baseline demographic and performance data for an initial base year, and demographic projections for three horizon years. By default, the model uses a base year of 2005 and horizon years of 2020, 2035, and 2050, though these can be modified.

At a minimum, the following key assumptions (as listed in the table) are required to define a study area. These inputs are all geographically dependent—they vary according to study area rather than according to policy or other methodological assumptions.

| Demographics | Transportation | Building Energy | Water |
|---|--|--|---|
| <ul style="list-style-type: none"> Baseline and projected population Baseline and projected households Baseline and projected jobs | <ul style="list-style-type: none"> Average per-capita vehicle miles traveled (VMT) Average LDV fuel economy Baseline GHG emissions per gallon of fuel Baseline auto ownership and maintenance costs per mile | <ul style="list-style-type: none"> Baseline average energy use per existing residential unit and commercial square foot (can be derived from total residential and commercial energy use) Baseline energy use by residential building type and commercial square foot GHG emissions per kilowatt-hour (kWh) of electricity GHG emissions per therm of natural gas Baseline energy costs per kWh and therm | <ul style="list-style-type: none"> Baseline residential water use per existing unit (can be derived from total water use) Baseline per-capita water use |

Study Area Selection Sheet. Input data are entered, stored, and loaded from the Study Area Selection sheet.

LAND USE OPTIONS

The Rapid Fire model analyzes up to four scenarios at a time. Each scenario consists of two components: a *land use option* and a *policy package*. The land use options vary the patterns of new growth, while the policy packages vary standards for automobile technology and fuel composition; building energy and water efficiency; and energy generation.

Land Use Options

The land use options all accommodate the same amount of projected population and job growth, but differ in how that growth is allocated. The user defines a land use option by varying the proportions of growth in each of three *Land Development Categories (LDCs)* – Urban, Compact, and Standard. The LDCs represent distinct forms of land use, ranging from dense, walkable, mixed-use urban areas that are well served by transit, to lower-intensity, less walkable places where land uses are segregated and most trips are made via automobile. Each LDC is associated with different travel behaviors and a different mix of housing types and commercial space profiles, as described generally on the next page.

The Rapid Fire model is loaded with four default land use options – *Business as Usual*, *Mixed Growth*, *Smart Growth*, and *Smart Growth Plus* – all which can be modified by the user. The figure at right shows the area of the Scenario Definition sheet in which land use options and the housing unit mixes of each LDC are defined. The definition and resulting housing type mix of an example land use option is outlined in the diagram on page 9.

Land Use Option Section of Scenario Definition Sheet.

Proportions for land use options and LDCs are set in the Land Use Option section of the Scenario Definition sheet.

LAND USE OPTIONS

Land Development Categories

The Urban, Compact, and Standard LDCs represent distinct forms of land use. Their general land use characteristics and transportation infrastructure are described below. These characteristics are all determined by model inputs that can be entered or adjusted by the user.

Land Use Characteristics

Transportation Infrastructure

URBAN Most intense and most mixed LDC, often found within and directly adjacent to moderate and high density urban centers. Virtually all 'Urban' growth would be considered infill or redevelopment. The majority of housing in Urban areas is multifamily and attached single family (townhome). These housing types tend to consume less water and energy than the larger single family types found in greater proportion in less urban locations.

Supported by high levels of regional and local transit service. Well-connected street networks and the mix and intensity of uses result in a highly walkable environment and relatively low dependence on the automobile for many trips.

Per-capita VMT range: ~ 1,500 to 4,000 per year.

COMPACT Less intense than Urban LDC, but highly walkable with rich mix of retail, commercial, residential, and civic uses. The Compact form is most likely to occur as new growth on the urban edge or large-scale redevelopment. Rich mix of housing, from multifamily and attached single family (townhome) to small- and medium-lot single family homes. Housing types in Compact areas tend to consume less energy and water than the larger types found in the Standard LDC.

Well served by regional and local transit service, but may not benefit from as much service as Urban growth, and is less likely to occur around major multimodal hubs. Streets are well connected and walkable, and destinations such as schools, shopping, and entertainment areas can typically be reached via a walk, bike, transit, or short auto trip.

Per-capita VMT range: ~ 4,000 to 7,500 per year.

STANDARD Represents the majority of separate-use auto-oriented development that has dominated the American suburban landscape over the past decades. Densities tend to be lower than Compact LDC, and are generally not highly mixed or organized to facilitate walking, biking, or transit service. Can contain a wide variety of housing types, though medium- and larger-lot single family homes comprise the majority of this development form; these larger single family tend to consume more energy and water than those in the Urban or Compact LDCs.

Not well served by regional transit service (typically), with most trips made via automobile.

Per-capita VMT range: ~ 9,500 to 18,000 per year.

Housing Unit Mix

The housing mix assumptions for the three LDCs lead to an overall mix of housing units for each land use option and time period. The default housing mix assumptions for the LDCs are intended to reflect existing land use patterns and policies, and thus remain constant for each LDC over time. Housing unit mix assumptions can be changed to represent shifts in housing demand over time, or to represent different market conditions among land use options.

Urban areas are comprised of multifamily and attached single family units. Compact areas contain the widest range of housing types, from multifamily and attached single family to small-lot single family units, with a small proportion of large-lot single family units. Standard development is dominated by large-lot single family units, with small proportions of other housing types. The LDC and housing unit mix assumptions for the default "Smart Growth" land use option are shown below.

Assumptions by Land Development Category

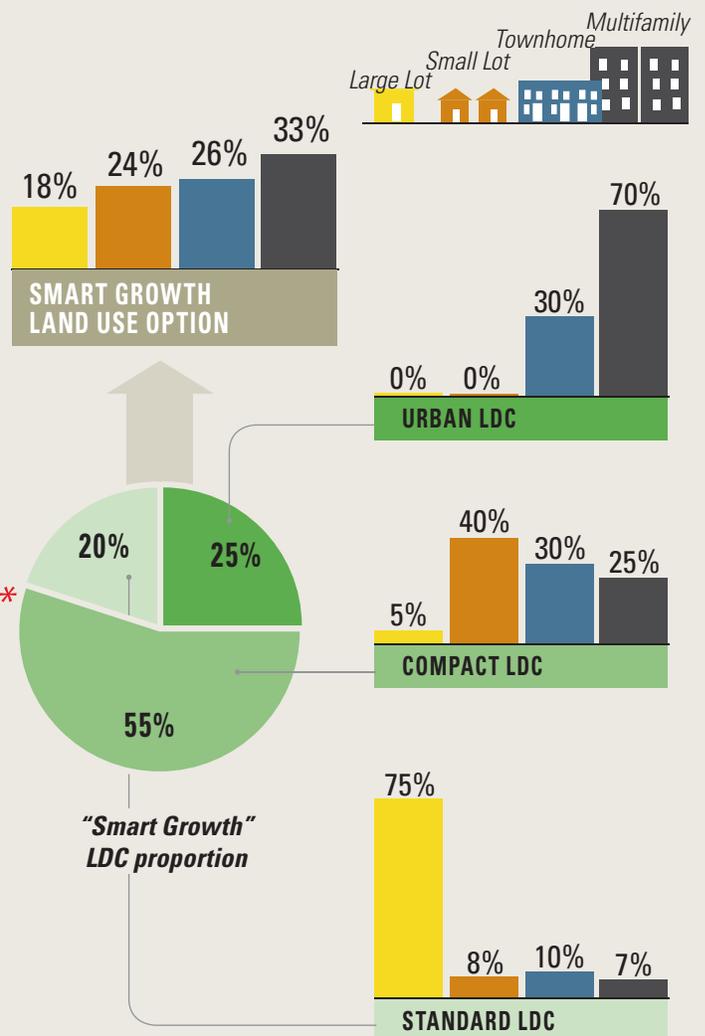

The housing unit mix assumptions are applied to the housing growth projected for each LDC (determined by the proportion of population growth allocated to the LDC within a scenario/time period) to produce housing counts by type.

Default Housing Mix Assumptions for LDCs

POLICY PACKAGE ASSUMPTIONS

Rapid Fire policy packages vary standards for automobile technology and fuel composition, building energy and water efficiency, and energy generation. *Auto and Fuel Technology* assumptions include those that guide vehicle efficiency, fuel emissions, and costs; *Building Efficiency* assumptions include building energy and water use standards as well as utility costs; and *Utility Portfolio* assumptions drive the carbon intensity of the power generation sector.

Policy-based input assumptions are grouped to represent different levels of improvement in each of these categories. While users can enter any combination of input assumptions, the policy packages allow users to instantly activate and switch between sets of assumptions to compare results. The components of the policy package categories are outlined in the table below.

As with the land use options, the policy packages can reflect a range of futures, from a business-as-usual case that continues current trends, to a progressive case that represents significant policy action. Users can enter values to define up to three alternate policy packages in each category.

Policy Package Selection Section of Scenario Definition Sheet. The policy packages are organized in sections on the 'Scenario Definition' sheet as shown below. Clicking on the buttons labeled A, B, and C at the top of each column loads input values to the 'Active Scenario' column located at the right of the 'Utility Portfolio' section (not shown). Users can select a 'Full Policy Group' of minimum, moderate, or high options, or they can select an option for each individual policy group. Once selected, the cells containing the active input values are highlighted in yellow (*). In this sample view, the 'moderate' level full policy group is selected.

| | 2050 | 17.66 lbs/gal | 16.68 lbs/gal | 9.81 lbs/gal | 17.66 lbs/gal | 16.68 lbs/gal |
| CO₂e EMISSION RATES | | | | | | |
| Residential & commercial building electricity | 2020 | 1.33 lbs/kWh | 1.13 lbs/kWh | 0.93 lbs/kWh | | |

Auto and Fuel Technology

- Internal combustion engine (ICE) vehicle fuel efficiency (miles per gallon)
- Fuel price (\$ per gallon)
- Well-to-wheels GHG emissions from fuel (lbs CO₂e per gallon)
- Tank-to-wheels GHG emissions from fuel (lbs CO₂e per gallon)
- Percent alternative/electric vehicles
- Battery electric vehicle efficiency (miles/kWh)
- Plug-in hybrid electric vehicle efficiency (miles/kWh)

Building Efficiency

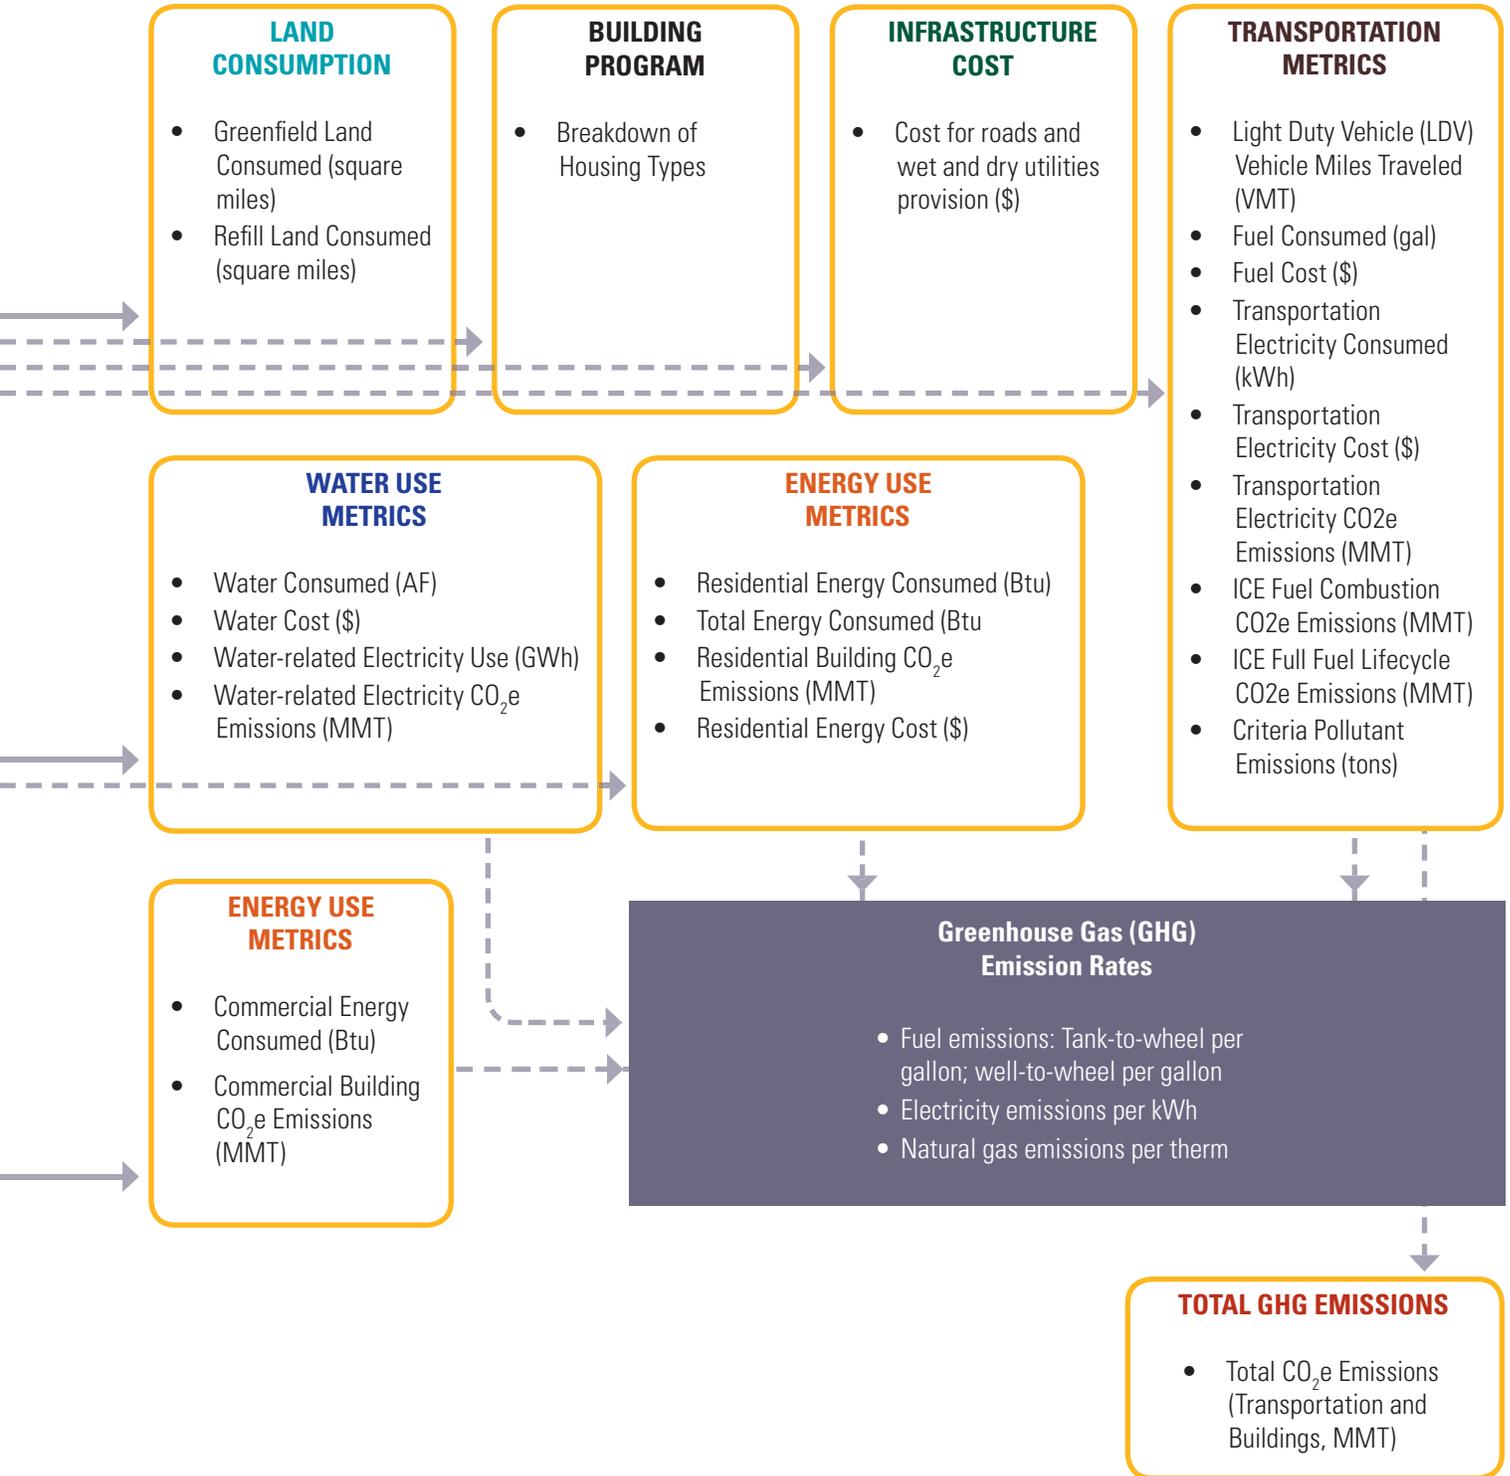

- New residential energy efficiency (% reduction from 2005 baseline use)
- New commercial energy efficiency (% reduction from 2005 baseline use)
- New residential water efficiency (% reduction from 2005)
- Energy efficiency/conservation improvements for base/existing residential building stock (year-upon-year % reduction)
- Energy efficiency/conservation improvements for base/existing commercial space (year-upon-year % reduction)
- Percent of base/existing residential buildings replaced each year
- Percent of base/existing commercial floorspace replaced each year
- Electricity price (\$ per kWh)
- Natural gas price (\$ per kWh)
- Water price (\$ per acre foot)

Utility Portfolio

- Residential & commercial building electricity emissions (lbs CO₂e per kWh)
- Residential & commercial building natural gas emissions (lbs CO₂e per therm)

OUTPUT METRICS

The following sections describe how the model uses input assumptions to calculate results in each of the metrics categories. The categories of output metrics are summarized below.

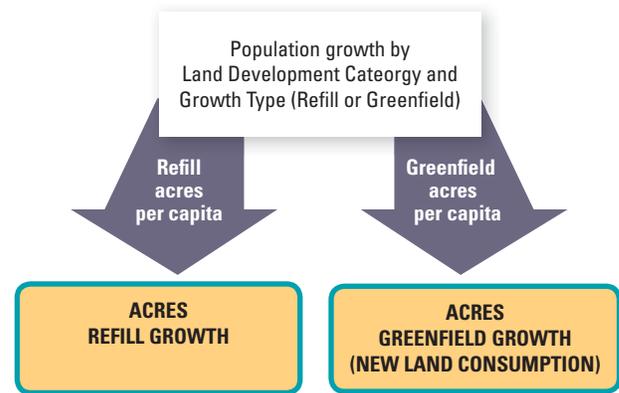

LAND CONSUMPTION

Land consumption includes all land that will be developed to accommodate population and job growth, including residential and employment areas, transportation alignments, open space, and public lands. The Rapid Fire model estimates land consumption using per-capita rates of land consumption, which vary by Land Development Category and the distribution of growth into greenfield or refill development. Default rates are based on studies of existing and planned development, and can be adjusted by the user.

Land consumption includes both refill and greenfield growth. Refill growth includes all development that may occur within the bounds of already-developed, urbanized areas, including infill, redevelopment, and greyfield and brownfield development. Greenfield growth refers to development that occurs on land that has not previously been developed or otherwise impacted, including agricultural land, forest land, desert land and other virgin sites. Only greenfield growth is counted towards the “new land consumption” of a scenario. The default land consumption characteristics for the three LDCs are as follows:

Urban: Comprised entirely of infill, redevelopment, greyfield, and brownfield growth, the Urban LDC consumes no greenfield acreage per capita.

Compact: Representing a combination of smart mixed-use growth in and around the urban edge (greenfield growth) as well as larger-scale greyfield growth within urban areas, the Compact LDC consumes a moderate acreage per capita. The land consumption rate for Compact growth is determined in part by the proportion of growth allocated to refill versus greenfield sites.

Standard: Generally consisting of lower-density, auto-oriented residential and commercial development, the Standard LDC consumes the highest acreage per capita since most, if not all, growth occurs on greenfield land. The new land consumption of a scenario is largely dictated by its proportion of Standard development.

The specific allocation of growth to either refill or greenfield land in each LDC and time period can vary by land use option. By setting assumptions for the proportion of refill growth and greenfield land consumption, as well as the intensity of greenfield growth in terms of acres consumed per capita, users can model a range of land-use policy options, from business-as-usual growth, to the application of urban growth boundaries, to a restriction of growth to refill parcels and sites only.

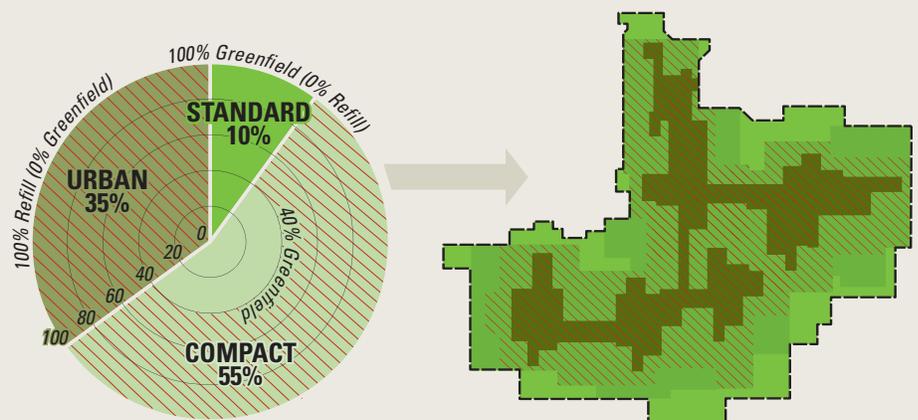

A land development profile resulting from the LDC mix of the Rapid Fire default “Smart Growth” land use option is illustrated in the figure below.

Refill Growth and Greenfield Land Consumption

The LDCs differ significantly in the population allocated to either refill growth or greenfield land. The assumed proportions for Urban and Standard are straightforward: all Urban development takes place as refill growth, while virtually all Standard development takes place on greenfield land. These characteristics are elemental to the Urban and Standard LDC definitions. The land consumption characteristics of Compact development, however, can vary significantly over time, by scenario, and by geographic area. The incremental land consumption rate of the Compact LDC is largely dependent on the assumed proportion of refill growth vs. development on new land.

Land Development Profile of “Smart Growth” Land Use Option (Illustrative Only)

| URBAN | COMPACT | STANDARD |
|--------------|--------------------|---------------------|
| Urban Refill | Compact Refill | Standard Greenfield |
| | Compact Greenfield | |

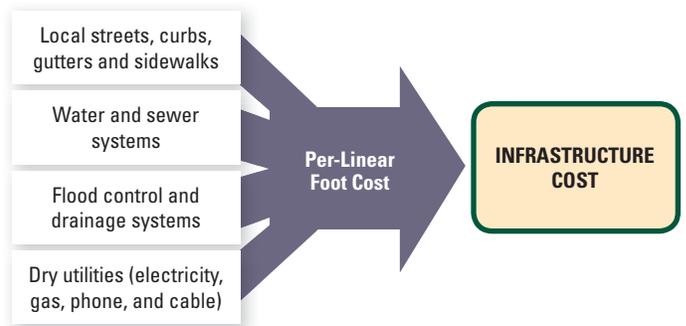

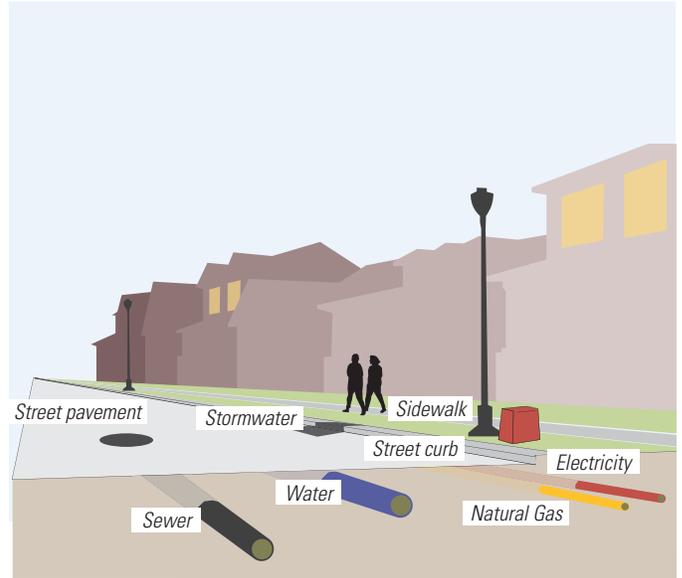

INFRASTRUCTURE COST

Infrastructure cost analysis allows users to compare the fiscal impacts of varying forms of development. The Rapid Fire model incorporates cost data from a number of sources to derive infrastructure cost factors on a per-housing unit basis according to land use option. Capital costs for the following infrastructure elements are included:

- Local streets, curbs, gutters, and sidewalks
- Water and sewer systems
- Flood control and drainage systems
- Dry utilities (electricity, gas, phone, and cable)

The per-unit infrastructure costs represent averages for the unit type mix of each land use option. Costs are estimated using per-linear foot cost data for each type of infrastructure. Dispersed development patterns require greater lengths of streets, sewers, and pipes because of the location of new development relative to already developed areas, as well as the distances between homes and other buildings. The default assumptions have been informed by the infrastructure cost results of various regional planning efforts, including the Sacramento Area Council of Government’s Blueprint planning and scenario modeling process.

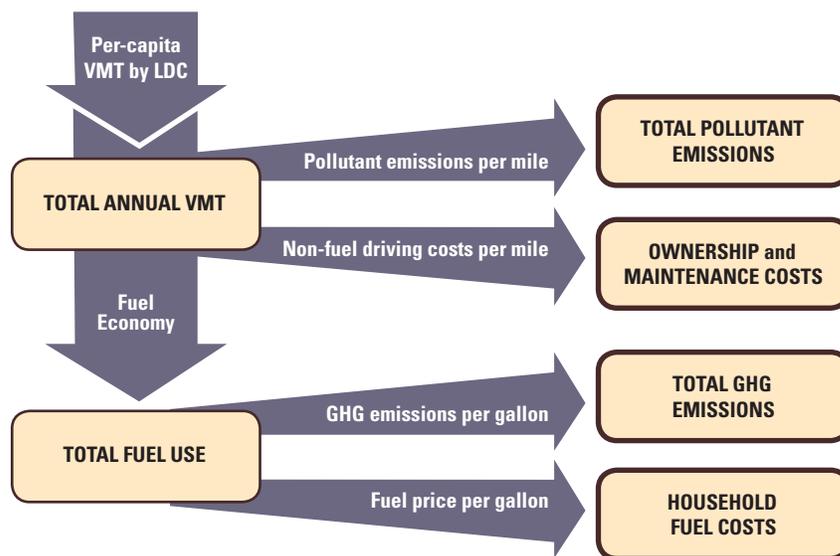

While the Rapid Fire model does not yet analyze the costs for operations and maintenance, these cost differences are expected to widen as the cost of ongoing maintenance (most often borne by local and regional agencies and operations) is included in future versions of the model. Future versions will also account for the incremental cost of infill and greyfield development and thus produce a more complete picture of infrastructure cost variations among land use patterns.

TRANSPORTATION

All transportation metrics in the Rapid Fire model are calculated on the basis of light-duty/passenger vehicle miles traveled (VMT). From VMT, the model estimates fuel use, greenhouse gas (GHG) and criteria pollutant emissions, and fuel and other driving costs.

Criteria pollutant emissions and non-fuel driving costs are calculated by applying per-mile assumptions to VMT. Fuel use is calculated according to vehicle fuel economy assumptions. In turn, GHG emissions are calculated based on per-gallon emission rates. All metrics are calculated on a total annual basis for every year leading up to the final horizon year. Per-capita and per-household averages are derived from annual and cumulative totals.

Vehicle Miles Traveled

The Rapid Fire model calculates VMT by applying assumptions about per-capita annual VMT to population growth. These assumptions, which differ by Land Development Category, are based on research and empirical evidence that per-capita VMT of both incremental (new) population and base year (existing) population vary based on the form of new growth.¹ Moreover, this variation is expected to change over time as areas become either more urban or compact, or more sprawling (determined on the proportions of LDCs in a scenario).

Variations in VMT across the scenarios is a result of year-by-year variation in per capita VMT by form of new growth (Urban, Compact, or Standard), and also the impact of new growth on the travel behavior of those already living in the study area in the base year (2005). For example, if one is living in an area 20 years from now that has seen increased transit service and/or new retail development in close proximity to their home or workplace, it is likely that they will drive less (and walk, bike, or take transit more) because daily destinations and services are closer.

It is an a priori assumption of the Rapid Fire model that requisite transportation investments go hand in hand with growth patterns, such that scenarios with a greater focus on Compact and Urban development would see increased transit, bicycle, pedestrian, streetscape, and livability investments. Conversely, scenarios dominated by Standard development would see large budget outlays to highway and road expansion.

Base and Increment VMT Rates

The Rapid Fire VMT assumptions are applied as adjustment factors to both incremental growth and the base year (existing) population. The user defines specific percentage increases or reductions from a baseline average VMT rate (which is specific to a study area).

For the growth increment, adjustment factors for each LDC within a land use option are applied to the baseline per-capita VMT rate. For the base population, adjustment factors are applied to total base year VMT. Varying factors are applied depending on the mix of LDCs in a specific scenario, and the amount of growth that occurs on refill or greenfield land (see the Land Consumption section for more information about refill and greenfield growth). The figure on the next page summarizes the relationship between scenario mix and the application of VMT adjustment factors.

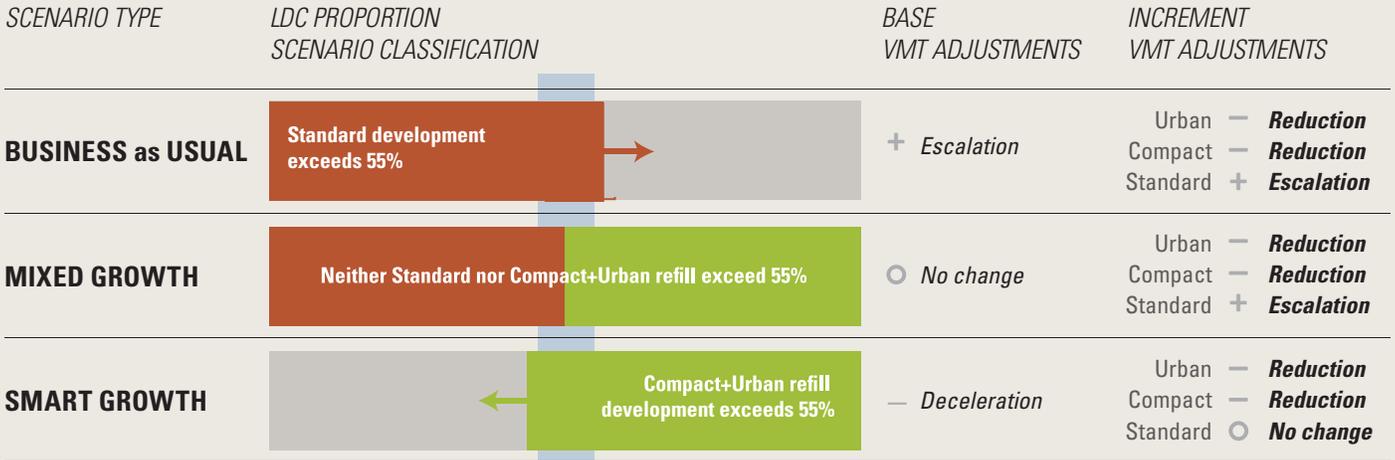

All VMT assumptions can be readily changed in the Rapid Fire model to test alternative hypotheses, integrate new empirical data, or calibrate to regional travel or other model outputs. For more detailed information about specific assumptions and their application, please refer to the *Rapid Fire Model White Paper and Technical Guide*.

TRANSPORTATION

Base and Increment VMT Adjustment Factors by Scenario Type.

If a scenario is more oriented towards Standard development, then VMT is calculated to increase at a greater rate than if a scenario is more focused towards Urban and Compact growth. Overall scenario orientation is determined using a "tipping point" range. If Standard development falls below the range, adjustment factors reflective of

progressively decreasing VMT are applied; conversely, if Standard development surpasses the range, factors reflective of increasing VMT are applied. If Standard development falls within the tipping point range, then driving behavior does not change further beyond the default rates.

Scenario Tipping Point Range:
45 - 55%

TRANSPORTATION

The Rapid Fire model calculates transportation fuel use, GHG and criteria pollutant emissions, and costs by applying policy-based assumptions to output VMT. Each metric is calculated on a total annual basis for all years in the model.

Fuel Use

LDV fuel consumption is determined by applying on-road average fuel economy assumptions (miles per gallon of gasoline equivalent², or MPG) to VMT in each year for each scenario. Fuel economy changes year upon year according to horizon-year projections. Policy-based projections significantly affect fuel consumption, and thus GHG emission and fuel cost results. Users can easily input and test alternate assumptions, such as compliance with California's Pavley Clean Car Standards or the federal CAFE standard, either in isolation or in combination with fuel carbon intensity assumptions.

Electric and other low-emission vehicles will play an important role in reducing GHG emissions. The Rapid Fire model can reflect their impacts in either of two ways: through the use of fuel economy and emission assumptions that implicitly capture the effects of their inclusion in the fleet³, or through the use of separate assumptions for electric and conventional (internal combustion engine) vehicles. More information about how the model estimates electric and alternative vehicle impacts can be found in the *Rapid Fire Model White Paper and Technical Guide*.

GHG Emissions

Transportation GHG emissions are calculated by applying carbon intensity assumptions, expressed in pounds of carbon dioxide equivalent (CO₂e) per gallon, to fuel consumption. Carbon intensity changes year upon year according to horizon-year projections. Projections can represent a range of standards, from a trend future in which carbon intensity remains constant or sees limited improvement, to a more aggressive policy-based future in which the carbon intensity of fuel declines significantly as low-carbon fuels, such as cellulosic ethanol and renewable biodiesel, comprise a higher proportion of fuel use.

The Rapid Fire model was designed to calculate emissions that occur upon fuel combustion ("tank-to-wheel" emissions), as well as those emitted during the full fuel lifecycle, from extraction and processing to transport and storage ("well-to-wheel" emissions). Users can look to either or both; typically, emission inventories compare tank-to-wheel emissions, although full well-to-wheel assessments are critical to developing climate change mitigation strategies. The Rapid Fire model is able to calculate both types of emission rates based on fuel mix assumptions, enabling an analysis of the role of fuel carbon intensity standards in meeting GHG reduction goals. More often, though, users will opt to model tank-to-wheel emissions on the basis of a baseline carbon intensity factor and projected reductions from it to each horizon year.

Fuel and other Driving Costs

The Rapid Fire model estimates three components of transportation costs, including fuel, auto ownership, and tires and maintenance. These costs are calculated separately using different assumptions. Fuel costs are calculated by multiplying fuel consumed by fuel price per gallon. Auto ownership and tire and maintenance costs are each calculated by multiplying VMT by an average price-per-mile factor. All per-gallon and per-mile prices change year upon year according to horizon-year projections.

Pricing Effects

Because fuel price, along with other driving costs, have been shown to have both short- and long-term effects on driving decisions, the Rapid Fire model allows users the option to "turn on" sensitivity to changes in per-mile driving costs to estimate changes in VMT due to pricing. Research into historic patterns has quantified relationships among the interrelated factors of VMT and automobile fuel economy with costs including fuel price and taxes; automobile ownership, insurance, and maintenance costs; and parking, toll, and congestion charges. The results, expressed as an "elasticity" of change in one factor with respect to change in another, can be used to estimate the effects of specific policy- or program-based assumptions on VMT.

RESIDENTIAL and COMMERCIAL BUILDING ENERGY

The Rapid Fire model calculates residential and commercial building energy use for both new and existing buildings. Scenarios vary in their building energy use profiles due to their building program and policy-based assumptions about improvements in energy efficiency.

Residential Energy Consumption

Residential energy use in the Rapid Fire model is calculated as a function of three basic sets of assumptions: a) average base-year energy use for existing units; b) base-year (2005) energy use for new units by building type; and c) reductions in building energy use resulting from advances in building energy efficiency policy and technology.

Energy Use of Base/Existing Buildings

Average per-household energy use for existing units is derived from total residential sector electricity and gas use and number of housing units in the baseline year (2005). The energy used by the population of existing units is expected to decline over time, as buildings are replaced, retrofitted, or upgraded. The extent of future energy savings due to each of these conditions are determined by user-specified rates.

Energy Use of New Buildings

Energy use for new units is calculated using per-unit factors for annual electricity and gas use. Reductions are applied to the baseline factors to reflect the assumption that, year-upon-year, new construction will be built to meet higher efficiency standards. It is also expected that new buildings can see further improvement over the time span of the model (for instance, a building built in 2011 may be retrofit by 2035 to meet even higher standards). The application of the energy use reduction assumptions applied to both new and existing units is shown in the flow chart on the following page.

Commercial Energy Consumption

As for residential energy use, commercial energy use in the Rapid Fire model is calculated as a function of three basic sets of assumptions: a) per-employee floorspace factors, b) baseline (2005) energy intensity factors, and c) reductions in building energy use resulting from advances in building energy efficiency policy and technology.

Energy Use of Base/Existing Buildings

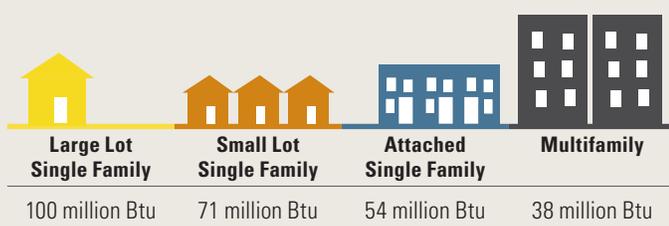

Average per-square foot energy use for existing commercial buildings is derived from total commercial sector electricity and gas use and a floorspace estimate for the baseline year (2005). The energy used by existing buildings is expected to decline over time, as buildings are replaced, retrofitted, or upgraded. The extent of future energy savings due to each of these conditions are determined by user-specified rates.

Energy Use of New Buildings

Energy use for new commercial floorspace is calculated using per-square foot energy intensity factors for annual electricity and gas use. Reductions are applied to the baseline factors to reflect the assumption that, year-upon-year, new construction will be built to meet higher efficiency standards. It is also expected that new buildings can see further improvement over the time span of the model (for instance, a building built in 2011 may be retrofit by 2035 to meet even higher standards). The application of the energy use reduction assumptions applied to both new and existing units is shown in the flow chart on the following page.

The amount of new commercial space in each scenario is calculated using assumptions about the number of employees by commercial space type (office, retail, or warehouse), and the amount of floorspace required per employee in each of the three Land Development Categories. Floorspace requirements are highest in the Standard LDC, and lowest in the Urban LDC. The number of employees by type, which is held constant for all scenarios, is projected based on demographic assumption inputs.

Baseline Annual Household Energy Use by Building Type*

* California averages, including residential electricity and natural gas use. Derived from the California Energy Commission Statewide Residential Appliance Saturation Survey (RASS), 2004.

Baseline Residential Energy Use. Because larger homes require more energy to heat and cool, home size is generally correlated with a household's overall energy consumption. Scenarios with a greater proportion of the Standard Land Development Category, which include primarily single-family detached homes, will require more energy – and produce more GHG emissions – than scenarios with a greater proportion of Compact or Urban areas, which include more attached and multifamily homes. Energy use also varies by climate zone, which can be reflected in the Rapid Fire model.

RESIDENTIAL and COMMERCIAL BUILDING ENERGY

RESIDENTIAL and COMMERCIAL BUILDING ENERGY

Greenhouse Gas Emissions

Building GHG emissions include total emissions from residential and commercial electricity and natural gas use. Emission results are calculated based on energy consumption and emission rates, which are assumed to vary according to the mix of resources used to generate energy. The baseline and projected emission rates are measured per unit of energy consumed (kilowatt-hour or therm), and include carbon dioxide, methane, and nitrous oxide emissions in units of carbon dioxide equivalent (CO₂e). The same emission rates are applied to the energy used by residential and commercial buildings.

Emission Rate Assumptions

Projections are made for the horizon years of 2020, 2035, and 2050, with rates following a straight-line trend in between. The emission rate for electricity generation can be expected to decline over time, while that for natural gas use can be expected to remain constant. As with all Rapid Fire assumptions, users can enter different inputs to test the results of different policy-based projections, for instance comparing the effects of achieving California's 33% Renewables Portfolio Standard (RPS) by 2020, or by a later date.

When available, absolute projections based on analyses specific to a state or region should be used. Because emissions from electricity are subject to a number of interrelated variables that can affect resource mix and emission rates into the future – including fuel price and availability, generation costs, energy use efficiency,

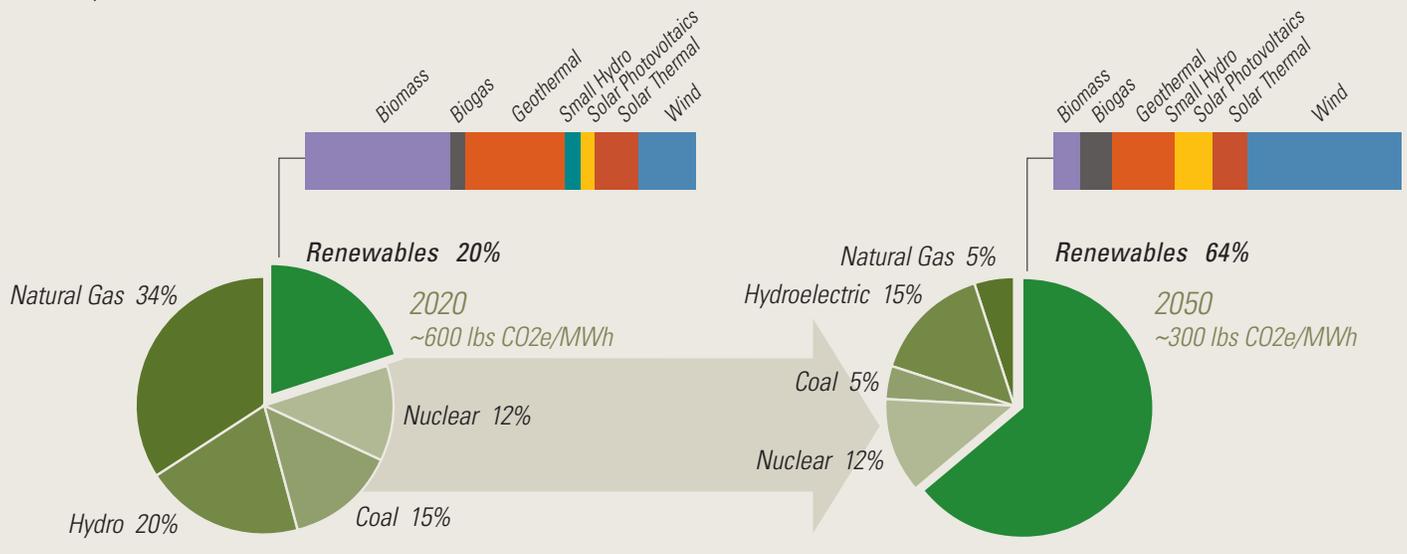

the market penetration of renewable energy technologies, and the amount of electricity imported from other areas – rates are technically challenging to estimate. In the absence of such projections, users can enter emission rate projections calculated as simple percentage reductions from the baseline emission rate. For a detailed discussion of energy emission rate assumptions and their application in the model, please refer to the *Rapid Fire Model White Paper and Technical Guide*.

Energy Costs

Residential and commercial energy costs are calculated on the basis of energy use and price assumptions. The model applies separate retail price factors to residential and commercial electricity and natural gas use. Price projection assumptions are expressed in constant dollars, and like all assumptions are entered for the horizon years of 2020, 2035, and 2050. Between horizon years, prices are assumed to follow a straight-line trend.

Electricity prices are expected to increase over time, in response to changes in the portfolio mix and other factors such as the cost of electricity generation resources, various infrastructure costs, overall supply and demand, and potential regulations. Electricity price projections can be estimated to correspond generally with the portfolio mix inherent to the chosen GHG emission rate assumptions, or estimated as simple percentage increases over the baseline price. Natural gas price projections can be estimated similarly.

Resource Mix and Emission Rates. Electricity greenhouse gas (CO₂e) emissions vary based on the mix of resources used. As the share of clean and renewable energy sources in the electricity generation portfolio is increased, the average electricity emission rate will decrease. Electricity emissions are estimated based on assumed rates in 2020, 2035, and 2050. The diagram below illustrates a hypothetical move toward a cleaner portfolio and lower emission rate.

RESIDENTIAL WATER USE

Water Consumption

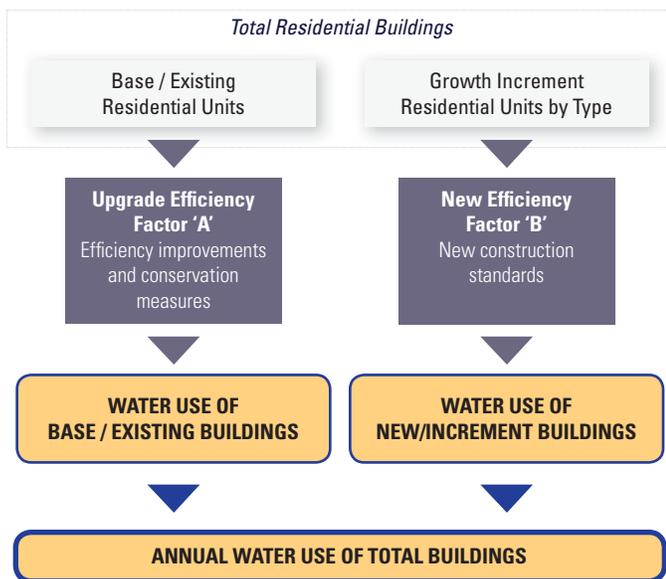

Residential water use in the Rapid Fire model is calculated as a function of three basic sets of assumptions: a) average base-year water use for existing units; b) base-year (2005) water use for new units by building type; and c) reductions in building water use resulting from advances in water efficiency policy and technology.

Water Use of Base/Existing Buildings

Average per-household water use for existing units is derived from total residential sector water use and housing units for the baseline year (2005). The energy used by the population of existing units is expected to decline over time, as water-saving measures are implemented. The extent of future energy savings due to each of these conditions are determined by user-specified rates – expressed as percentage reductions from baseline use – to each horizon year.

Water Use of New Buildings

Water use for new units is calculated using annual per-unit usage factors, which vary by building type. Reductions are applied to the baseline factors to reflect the assumption that, year-upon-year, new homes will be built with the technology to meet higher efficiency standards. It is also expected that new buildings can see further improvement over the time span of the model (for instance, a building built in 2011 may be upgraded by 2035 to meet even higher standards). The application of the water use reduction assumptions applied to both new and existing units is represented in the flow chart below.

Water Costs

Residential water costs are calculated on the basis of water use and retail water price assumptions. Water price projections are expressed in constant dollars per acre-foot, and like all assumptions are made for the horizon years of 2020, 2035, and 2050. Between horizon years, prices are assumed to follow a straight-line trend.

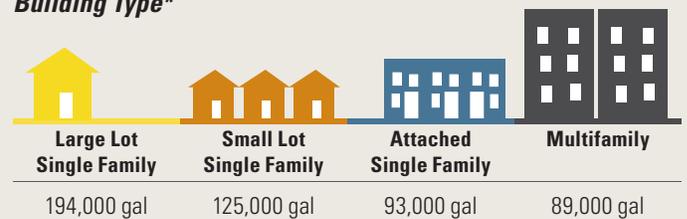

Water prices are expected to increase over time in response to limited supply and the potential application of pricing strategies to promote water conservation. Users can make absolute price assumptions based on specific policies, or assume a year-upon-year rate of increase.

GHG Emissions from Water-Related Energy Use

Water-related GHG emissions result from two main categories of energy use: a) system uses, including the transport, treatment, and distribution of water consumed; and b) end uses, including all uses of water that occur within homes (e.g., water heating).²² The Rapid Fire model calculates energy use and emissions for system uses, while emissions resulting from end uses are accounted for as a component of residential and commercial building energy emissions.

Baseline Water Use. Because larger homes with larger yards require more water for landscape irrigation, lot size is generally correlated with a household's overall water consumption. Scenarios with a greater proportion of the Standard Land Development Category, which include primarily single-family detached homes, will require more water – and produce more GHG emissions – than scenarios with a greater proportion of Compact or Urban areas, which include more attached and multifamily homes. Outdoor water needs also vary with climate. For California, the Rapid Fire model estimates outdoor water needs according to reference evapotranspiration (climate-based irrigation factors) for different geographic areas.

2005 Annual Household Water Use by Building Type*

* California statewide baseline average consumption figures include indoor and outdoor water use. Indoor use is based on per-capita averages; outdoor use is based on generalized assumptions about landscape area and irrigation requirements.

MODEL RESULTS

Viewing Model Results

Users can view model outputs through the model's static results summary (the "Results" sheet) or the automated interface of the "Interactive Results" sheet. The automated interface allows users to customize the results display according to the following parameters:

- Horizon year (2020, 2035, or 2050)
- Annual (single-year) or cumulative (multiple-year leading up to horizon year) metrics
- Total, per capita, or per household basis for metrics
- Comparison of annual metrics against historic baseline year (1990 or 2005)

Below is a sample view of the "Interactive Results" sheet.

RESULTS (Interactive)

Study Area: United States

- 1 Select a horizon year for which to show results: 2020 2035 2050
- 2 Select ANNUAL or CUMULATIVE results: Annual Cumulative
- 3 Select total, per capita, or per household results: TOTAL per Capita per Household
- 4 Select a historical baseline year against which to compare selected horizon year results: 1990 2005
- 5 Click to see results: CLICK for RESULTS
- 6 If needed, return to Policy Option Selection worksheet to change policy options. Return to POLICY OPTIONS

THE VISION CALIFORNIA PROCESS

The development and application of the Rapid Fire model is part of the Vision California process, an unprecedented effort to explore the role of land use and transportation investments in meeting the environmental, fiscal, and public health challenges facing California over the coming decades. Funded by the California High Speed Rail Authority (cahighspeedrail.ca.gov) in partnership with the California Strategic Growth Council (www.sgc.ca.gov), Vision California will:

- Highlight the unique opportunity presented by California's planned High Speed Rail network in shaping growth and other investments.
- Frame California's development issues in a comprehensive manner, illustrating the role of land use in meeting greenhouse gas (GHG) reduction targets through robust analysis.
- Illustrate the connections between land use and other major challenges, including water and energy use, housing affordability, public health, farmland preservation, infrastructure provision, and economic development.
- Clearly link land use and infrastructure priorities to mandated targets as set forth by AB 32, SB 375, and the California Air Resources Board (CARB).
- Produce scalable tools, for use by state agencies, regions, local governments, and the non-profit community, which can defensibly measure the impacts of land use and transportation investment scenarios.
- Build upon Blueprints and other regional plans to produce statewide growth scenarios that go beyond regional boundaries and assess the combined impact of these plans.
- Connect state and national goals for energy independence, energy efficiency, and green job creation to land use and transportation investments.

Vision California is driven in part by the challenges set forth by the 2006 passage of the California Global Warming Solutions Act (AB 32), which sets aggressive targets for the reduction of greenhouse gas emissions (GHGs). The project is designed to provide critical context for the implementation of Senate Bill 375 (SB 375) and land use-related GHG-reduction targets for local governments, as it will illustrate and comprehensively measure the role of land use and SB 375-mandated regional "Sustainable Communities Strategies" in meeting AB 32 GHG targets.

Two new scenario development and analysis tools are being used to compare physical growth alternatives – the Rapid Fire model, and the 'Urban Footprint' map-based model. These related tools serve distinct purposes: while the spreadsheet-based Rapid Fire model quickly produces metrics that bracket the range of potential impacts, the map-based Urban Footprint model produces a more refined analysis that is greatly sensitive to land use and demographic characteristics.

The Urban Footprint Map-Based Model. Currently under development, the Urban Footprint model uses geographic information system (GIS) technology to create and evaluate physical land use-transportation investment scenarios. Scenarios are defined through the application of 'Place Types' to the environment. The model's suite of Place Types represents a complete range of development types and patterns, from higher density mixed-use centers, to separated-use residential and commercial areas, to institutional and industrial areas. The physical and demographic characteristics associated with the Place Types are used to calculate the impacts of each scenario. Output metrics will include: land consumption; infrastructure cost (capital as well as operations and maintenance); building energy and water consumption, cost, and associated CO₂ emissions; public health impacts; vehicle miles traveled and all related fuel, GHG, and pollutant emissions; and non-auto travel mode share and other related travel metrics.

ENDNOTES

Endnotes

1. For a thorough description of the Rapid Fire VMT modeling methodology, including an analysis of VMT in sample LDC areas and a discussion of relevant studies, please refer to the *Rapid Fire White Paper and Technical Guide*.
2. Consistent with regulatory targets, all assumptions and results for fuel use, fuel economy, and fuel emissions in the Rapid Fire model are expressed in terms of gallons of gasoline equivalent.
3. California's AB 1493 Clean Car Standard and Low-Carbon Fuel Standard, for example, both assume that growing shares of electric and other low-emission vehicles in the on-road fleet are necessary to reach targets.

* Denotes an optional input which was not applied in calculating the output metrics presented in this report.

Transportation Emissions

- Baseline fuel emissions, full lifecycle (well-to-wheel) for total fleet, internal combustion engine vehicles alone*, and alternative/electric vehicles alone*
- Baseline fuel emissions, combustion (tank-to-wheel) for total fleet, internal combustion engine vehicles alone*, and alternative/electric vehicles alone*
- Percent gasoline vs. diesel in liquid fuel mix
- Composition of gasoline and diesel fuel mix
- Criteria pollutant emissions per mile traveled

Building Energy Emissions

- Electricity generation emissions (lbs/kWh)
- Natural gas combustion emissions (lbs/therm)
- Electricity generation emissions in horizon years (lbs/kWh)
- Natural gas combustion emissions in horizon years (lbs/therm)

Residential Building Energy Use & Price

- Baseline average annual energy use per unit for base/existing population
- Annual energy use by building type
- Housing unit replacement rate for base/existing housing stock
- Upgrade efficiency reduction factor 'A' for base/existing housing stock
- New efficiency reduction factor 'B' for replacement units of base/existing housing stock
- Upgrade efficiency reduction factor 'C' for replacement units of base/existing housing stock
- New efficiency factor 'D' for new units of the growth increment
- Upgrade efficiency factor 'E' for new units of the growth increment
- Baseline residential electricity price
- Baseline residential gas price
- Residential electricity price in horizon years
- Residential gas price in horizon years

Commercial Building Energy Use & Price

- Non-farm job proportion by floorspace-type category
- Floorspace per employee by category for each LDC
- Commercial space replacement rate for base/existing housing stock
- Baseline average annual energy use per square foot for base/existing commercial space
- Annual baseline energy use for new commercial space
- Replacement rate for base/existing commercial space
- Upgrade efficiency reduction factor for base/existing commercial space
- New efficiency reduction factor for replacement commercial space
- Upgrade efficiency reduction factor for replacement commercial space
- New efficiency factor for new floorspace of the growth increment
- Upgrade efficiency factor for new floorspace of the growth increment
- Baseline commercial electricity price
- Baseline commercial gas price
- Commercial electricity and gas price in horizon years

Residential Building Water Use

- Baseline per capita indoor water demand by building type
- Baseline per-unit outdoor water demand by building type
- New residential water efficiency (% reduction from 2005)
- Baseline water price (\$/acre foot)
- Water price in horizon years (\$/acre foot)

Residential Water-Related Energy Use and Emissions

- Average water energy proxy (electricity required per million gallons water used)

* Denotes an optional input which was not applied in calculating the output metrics presented in this report.
